

Introduction to the Vernier Photogate Using LabQuest App

The purpose of this document is to provide a tutorial on the use of Vernier Photogates with LabQuest App data-collection software. This combination of hardware and software has many applications in physics and physical science. The equipment can be used to study the motion of toy cars, dynamics carts, and objects in freefall. It can be used to measure the initial launch velocity of a projectile or to accurately measure the period of a pendulum. The wide variety of applications makes the sensor extremely valuable in the classroom.

The photogate works by projecting an infrared beam from one arm of the sensor to the other arm. When the beam is blocked the sensor stops sending a signal, which illuminates an LED on the top of the gate as well as triggering the LabQuest to display a blocked message in the meter display.

The sensor has several different modes of use that are important to understand. These modes are based on the blocking and unblocking events. Some modes are very simple. Some are more complex. An example of a simple mode is the Gate Mode. In this mode, the photogate simply records how long the gate is blocked. Knowing that time and the length of the object that went through the gate, you can determine the average speed through the gate. An example of a more complex mode is Motion Timing. In this mode, the photogate beam is repeatedly blocked and unblocked by an object such as the spokes of a pulley. The times from these events along with the knowledge of the spoke spacing allows you to obtain position, speed and acceleration data.

The purpose of this tutorial is to show all the ways that to use the Vernier Photogate to collect data with a LabQuest.

Objectives

- Collect and interpret data from a Vernier Photogate using a LabQuest.
- Use the Gate Timing mode

- Use the Pulse Timing mode
- Use the Pendulum Timing mode
- Use the Gate and Pulse Timing mode
- Use the Motion Timing mode
- Use Digital Events mode

Materials

Vernier LabQuest Vernier Photogates Vernier Picket Fence (optional)
meter stick or ruler

Part I Gate Timing

Gate timing begins when the photogate is first blocked. The timing will continue until the gate is unblocked. The duration of the interruption is thus timed. If the length of the object is entered in the Length of Object field, the speed is calculated.

The following diagram represents the gate state during a blocking event. The diagram shows a horizontal line representing time. The vertical position represents the gate state. When the line is high, the gate is unblocked. When the line is low, the gate is blocked. Time T_1 is the time that software records as the gate being blocked. So the diagram shows that the gate is initially unblocked, then blocked, and then unblocked again.

Speed calculation in Gate mode relies upon knowing the length of the object going through the gate. For some objects, e.g. note cards, this is not a problem, but other objects might be more challenging. For example, if you rolled a marble through the gate, you would need to know the diameter or radius of the ball that went through the beam. Inaccuracies in that number enter errors into the speed measurements; therefore alignment in this type of experiment is important.

When using the Gate mode, you can add multiple photogates to measure the speed of an object through those gates.

1. Connect a Vernier Photogate to the LabQuest. Make sure the shutter on the inside of the photogate leg is open. (If present.)
2. First verify that the photogate and software is working by placing your hand in the photogate beam. The red LED on the top of the gate should illuminate and the LabQuest should display Blocked in the Gate State meter view of the LabQuest application. If this does not happen, check all of your connections and restart the

LabQuest if necessary.

3. Select Data Collection from the Sensors menu. Then select Gate from the Photogate Mode drop down menu.
4. Tap in the box and change the field to 1 m and tap OK.
5. Start data collection and use your thumb to block the photogate beam for a count of one. e.g. “one thousand one.” Unblock the photogate. Wait momentarily, and then block it again for a count of two. Unblock the photogate, block it again for a count of three, and unblock it. Click the Stop button.
6. Examine the data table by tapping on its tab. The third column shows the Gate Time, i.e. how long the gate was blocked. How close were you to blocking the gate for 1, 2, and 3 s?
7. The Velocity column assumes that the object length was 1 m. Use that length and the Gate Time to calculate what would have been the speed of a 1 m object going through the gate. How do your calculations compare to the Velocity column of the data table?
8. Measure the width of your index finger at the first knuckle in meters and enter the value in the Photogate Timing screen found in the Data Collection menu. Invert the photogate, open side up, and practice passing your finger through the photogate. Try to keep your first knuckle in the beam as it passes through the photogate.
9. Start data collection. Pass your finger through the gate. Continue for a total of 10 trials, trying different speeds. After 10 trials stop data collection. Data will be collected in terms of time and then a calculated speed will be displayed in the data table as well. Real time graphs will show your velocities as you pass your finger through. (Click the Autoscale Once option in the Graph menu, if needed, to see all of your times and velocities.)

Part II Pulse Timing

Pulse Timing refers to the measurement from one blocking event to the next.

If you are using two photogates, the first blocking event which starts the timing will come from the photogate in the first digital channel, e.g. DIG1, and the stopping event will come from the photogate in the second channel, e.g. DIG2. A great example of this mode is measuring the average speed as a cart as it moves from the top of a ramp to the bottom.

If you are using a single photogate, the starting and stopping events will occur through the one photogate. An example of this use would be the timing of the period of a turntable. An object on the turntable would block the photogate, make its circular path and block it again.

In the following, we'll investigate both scenarios.

10. Repeat Step 3 but select Pulse. Set the photogate distance to 1 meter in the Distance between gates box.
11. Start data collection and pass your index finger through the photogate. Count “one thousand one” and pass your finger through the gate again. LabQuest will record the time for successive blocking of the photogate and automatically stop data collection after two blocked blocking events.
12. Repeat step 11 waiting different amounts of time between blockings of the photogate. Does your collected data support the motions that you completed?
13. Connect a second photogate to the interface. Repeat Step 10.
14. The two-gate pulse timer setup measures the length of time between one photogate being blocked and a second photogate being blocked. Start data collection and pass your finger through the photogate in the first channel, e.g. DIG1, count “one thousand one” and then move your finger through the second gate. Wait momentarily, and then block the first again, count to two and run your finger through the second photogate. Block the first again, count to three and run your finger through the second photogate. Click the Stop button.
15. Examine the data table. The fourth column shows the time from gate 1 to gate 2. How close are these times to your estimated times of 1, 2, and 3 s?
16. Be careful to have the photogates positioned properly. The object must pass through the photogate connected to DIG 1 first, then through DIG 2 photogate. If the reverse direction is used, then the object will have to pass through the gate again in order to record a time. And this will be an incorrect value.

Part III Pendulum Timing

The Pendulum Timing mode uses a single photogate attached to a LabQuest. The timing will begin when the photogate is first interrupted. The timing will continue until the photogate is interrupted twice more, so that you get the time for a complete swing of a pendulum or other oscillating object.

Use of this mode will give you very accurate measurements of pendula periods.

17. Connect a single photogate to the LabQuest.
18. Repeat Step 3 and select Pendulum. Tap Ok.
19. Start data collection.
20. Move your finger through the photogate, count “one thousand one”, move your finger back through the photogate, count “one thousand one” again and now pass your finger back through the gate a third time.
21. Repeat Step 19 two more times so that you have three period measurements. Click the Stop button
22. Examine the Period column of the data table. How closely were you to simulating a motion that has a period of 2 seconds?

Part IV Gate and Pulse Timing

Gate and Pulse Timing is accomplished by combining the process of a gate timer, measuring the time a photogate is blocked, with pulse timing, measuring the time between successive blockings of the photogates. This allows the measurement of the speed of an object at each gate and the acceleration the object is undergoing by using the velocities and the time measured for the object between photogates.

23. Connect two photogates to the LabQuest.

24. Repeat Step 3 and select the Gate and Pulse. Enter 1 m for the length of the object.
25. Invert the photogates on the table.
26. Begin data collection and pass your index finger slowly through the photogate attached to the first digital port on the interface, e.g. DIG1. Now pass your finger quickly through the second photogate. Stop data collection.
27. Since you moved your finger slowly through the first gate and quickly through the second gate, the software should have reported back a positive acceleration. Was that the case in your example?
28. Repeat Step 26 but this time move quickly through the first gate and slowly through the second gate. This action should produce negative acceleration. Was that true in this run?

Part V Motion Timing

When you start the LabQuest, the default data-collection mode for the photogate is Motion Timing. In this mode the LabQuest records a series of blocking events from an object that has a repeating transparent and opaque pattern.

Two good examples of objects that utilize this mode are the Vernier Picket Fence (a plastic bar with a series of opaque and transparent bars) or the Vernier Ultra Pulley.

If you are using a Vernier Picket Fence (see below), the equipment records 8 blocking events, one for each black bar. The distance from one leading black bar to the next is 5 cm. Using the times from the blocking events and the 5 cm spacing, position, speed and acceleration data are determined. When the picket fence is dropped through the photogate, the plot of speed vs. time produces a straight line and the slope of the straight line is the acceleration due to gravity.

If you are using a pulley instead, the pulley spokes block and unblock the beam. Using the blocking times and knowing the circumference of the pulley, the software can again determine position, speed and acceleration. A good example of the use of the pulley is with an Atwood's machine.

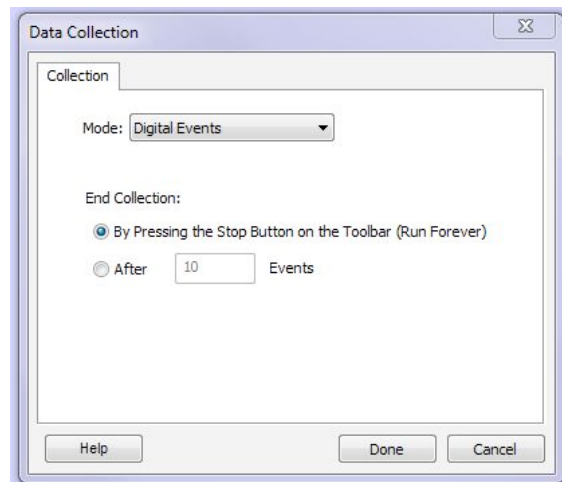

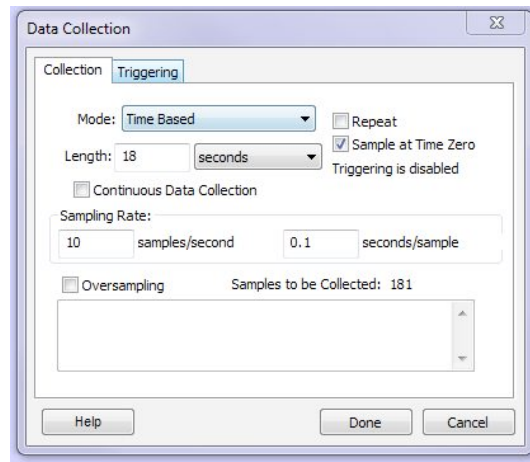

29. Connect one photogate to the LabQuest.
30. Repeat Step 3 and select Motion. Be sure that the Vernier Picket Fence button is selected. Tap Ok.
31. Invert the photogate and start data collection. LabQuest will display a spinning flower over the graph. This shows that the LabQuest is waiting for something to record. It will start when the photogate beam is broken and will stop after 8 blocking events. Take your hand and spread your 4 fingers apart. Pass them through the photogate. Now pass your four fingers back through the photogate. This gives 8 events and data collection will automatically stop. Look at your distance graph. Why does the distance increase? What is the LabQuest measuring?
32. Repeat step 30, but vary the speed as you pass your hand (or fence) through the gate. What does your graph look like now? Does it match your motion? What else does the graph tell you?
33. If you have access to a Picket Fence, hold it vertically above the photogate. Click the Collect button and then drop it through the gate. Describe the position and speed graphs.

Part VI Digital Events

If you connect an auto-ID photogate to the LabQuest, a default experiment will be set up. The default will be to collect motion data (described above) and it will be assumed that a Vernier Picket Fence will move through the photogate. If you choose the Data Collection option in the Sensors menu, the Data Collection dialog box will tell you more about the experiment.

To see an example of the Digital Events mode, Choose the Data Collection option from Sensor menu. This Data Collection dialog box will appear. Choose the Mode None. This will show the message Digital States only below the Photogate Mode menu. At the bottom of the screen, notice that there is a section labeled “End Collection.” Data collection will stop with the Stop button, or after a set number of events, which is chosen by the user.

This mode is very useful in other experiments. Suppose that you wanted to collect force data (an analog measurement) along with photogate data (a digital measurement). When you set the mode to Digital Events, the analog channel is sampled each time that there is blocking or unblocking transition on the photogate. If you instead set the mode to Time Based, the analog signal and digital signal are sampled independently. The following two data tables demonstrate the difference between these modes.

	Latest

TIPS

Experiment Information

1. The photogate can also be used as a laser gate. A mechanical shutter, located on the inside of the photogate arm is used to block the internal gate, making the use of the outside gate possible. A laser is needed to provide the signal for the photogate. This enables you to make a gate as large as you need it.
2. The experiment files for the different modes of photogate timing are included with *Logger Pro*. It is recommended that you use these files to ensure correct setup of the photogate(s).

Sensor Information

1. The photogate may have a mechanical shutter on the inside of the arm of the gate. If the photogate is not registering blocking and unblocking events, check to see that this shutter is open, and not closed.
